Summary
Biometric techniques are gaining importance for personal authentication and identification as compared to the traditional authentication methods. Biometric templates are vulnerable to variety of attacks due to their inherent nature. When a person’s biometric is compromised his identity is lost. In contrast to password, biometric is not revocable. Therefore, providing security to the stored biometric template is very crucial. Crypto biometric systems are authentication systems, which blends the idea of cryptography and biometrics. Fuzzy vault is a proven crypto biometric construct which is used to secure the biometric templates. However fuzzy vault suffers from certain limitations like non-revocability, cross matching. Security of the fuzzy vault is affected by the non-uniform nature of the biometric data. Fuzzy vault when hardened with password overcomes these limitations. Password provides an additional layer of security and enhances user privacy. Retina has certain advantages over other biometric traits. Retinal scans are used in high-end security applications like access control to areas or rooms in military installations, power plants, and other high risk security areas. Multimodal biometric system performance is well compared to single modal biometric systems. The proposed multi modal biometric fuzzy vault includes combined feature points from retina and Iris. Iris and retinal capturing cameras can be combined as a single device to improve user convenience. The combined vault is hardened with user password for achieving high level of security. The security of the combined vault is measured using min-entropy. The proposed password hardened multi biometric fuzzy vault is robust towards stored biometric template attacks.

Key words:
Biometric Template Security, Crypto Biometric Systems, Hardening Fuzzy Vault, Min-Entropy.

1. Introduction
The biometric crypto system utilizes the advantages of both biometrics and cryptography for ensuring high security. Some of the applications include financial transactions, border security and military applications. Biometrics and cryptography can be combined in two methods namely Biometric based key release and Biometric based key generation.

Biometric based key release method involves the separation of biometric matching from cryptography. If the biometric templates are matched successfully then cryptography key is released. eg. Smart card. Here biometric plays the role of a wrapper. In biometric based key generation method, biometrics and cryptography are combined together at a much higher level. In this method the secret key is extracted from the combined key and biometric template. A fuzzy vault is a biometric based key generation cryptographic construct. This work focuses on the mixing of two different biometric modalities to construct the multimodal fuzzy vault. Iris and retina are utilized to construct the multimodal biometric vault.

1.1 Advantages of retina
Retinal scan captures the pattern of blood vessels in the eye. Retina as a biometric has certain merits compared to other biometrics. It is highly secure and uses a stable physiological trait. Retina is very difficult to spoof. Retinal patterns are different for right and left eye. They are unique even for identical twins. More over, retinal patterns do not change with age. Unlike other biometric traits, the image will not fall on the retina for dead person. Retina is located deep within ones eyes and is highly unlikely to be altered by any environmental or temporal conditions. Therefore retina is best suited biometric for high security systems. Some of disadvantages of iris biometrics can be eliminated by combining it with retina.

1.2 Construction of Fuzzy vault
Fuzzy vault is a cryptographic construct proposed by Juels and Sudan [2]. This construct is more suitable for applications where biometric authentication and cryptography are combined together. Fuzzy vault framework thus utilizes the advantages of both cryptography and biometrics. Fuzzy vault eliminates the key management problem as compared to other practical cryptosystems. In fuzzy vault framework, the secret key S is locked by G, where G is an unordered set from the biometric sample. A polynomial P is constructed by encoding the secret S. This
polynomial is evaluated by all the elements of the unordered set G. A vault V is constructed by the union of unordered set G and chaff point set C which is not in G.

\[ V = G \cup C \]

The union of the chaff point set hides the genuine point set from the attacker. Hiding the genuine point set secures the secret data S and user biometric template T.

The vault is unlocked with the query template T'. T' is represented by another unordered set U'. The user has to separate sufficient number of points from the vault V by comparing U' with V. By using error correction method the polynomial P can be successfully reconstructed if U' overlaps with U and secret S gets decoded. If there is not substantial overlapping between U and U' secret key S is not decoded. This construct is called fuzzy because the vault will get decoded even for very near values of U and U' and the secret key S can be retrieved. Therefore fuzzy vault construct become more suitable for biometric data which show inherent fuzziness hence the name fuzzy vault as proposed by Sudan [2].

The security of the fuzzy vault depends on the infeasibility of the polynomial reconstruction problem. The vault performance can be improved by adding more number of chaff points C to the vault.

1.3 Multimodal Fuzzy Vault

Multimodal fuzzy vault performs well compared to the traditional unibiometric systems [5]. Multi biometrics provides better recognition accuracy, enhances very high security, flexibility and user convenience [13, 14]. It can be used in applications like financial transactions, for securing secret cryptographic keys, email communications etc.

Biometric templates are not revocable when compromised like passwords [12]. A template represents a set of salient features that summarizes the biometric data of an individual. A compromised template would mean the loss of a user's identity [9,10]. A potential abuse of biometric identifiers is cross-matching [11]. Therefore biometric template security is very crucial to protect user privacy. It is very difficult for an attacker to compromise multi biometric modalities.

The proposed multimodal fuzzy vault contains point set from two different biometric modalities say Iris and retina namely K_i and K_r. Then Chaff points are added to the vault to conceal the genuine points.

\[ V = (K_i \cup K_r \cup C) \]

The Chaff points are generated in such a way that they do not lie on K_i and K_r. In this proposed vault the secret S is locked by two unordered sets U_i and U_r.

The following Table I shows the notations used.

1.4 Limitation of Fuzzy Vault Scheme

Fuzzy vault being a proven scheme has its own limitations [5].

(i) If the vault is compromised, the same biometric data cannot be used to construct a new vault. Fuzzy vault cannot be revoked. Fuzzy vault is prone to cross-matching of templates across various databases.

(ii) Due to the non-uniform nature of the biometric features it is easy for an attacker to develop attacks based on statistical analysis of the points in the vault.

(iii) The vault contains more chaff points than the genuine points. This facilitates the attacker to substitute few points from his own biometric feature. Therefore the vault authenticates both the genuine user and the imposter using the same biometric identity. As a consequence, the false acceptance ratio of the system increases.

(iv) Original template of the genuine user is temporarily exposed. During this exposure the attacker can glean the template.

To overcome the limitations of fuzzy vault, password is used as an additional authentication factor. The proposed multimodal fuzzy vault is hardened by password. This enhances the user-privacy and adds an additional level of security.

1.5 Fuzzy Vault Hardening

The hardened fuzzy vault overcomes the limitations of non-revocability and cross-matching by introducing an additional layer of security by password. If the password is
compromised the basic security and privacy provided by the fuzzy vault is not affected. However, a compromised password makes the security level same as that of a fuzzy vault. Therefore, security of the password is crucial. It is very difficult for an attacker to compromise both the biometric template at the same time. The proposed method constructs a multimodal biometric fuzzy vault using the feature points extracted from retina and iris. The multimodal biometric fuzzy vault is then hardened using the password.

**Steps in hardening scheme**:

1. A random transformation function is derived from the user password.
2. The password transformed function is applied to the retina template.
3. The password transformed function is applied to the iris template.
4. Fuzzy vault framework is constructed to secure the transformed templates by using the feature points from both the retina and iris.
5. The key derived from the same password is used to encrypt the vault.

Figure 1 depicts the steps involved in the construction of the password hardened multimodal biometric fuzzy vault.

The organization of the paper is as follows: Section II elaborates the construction and operation of fuzzy vault. Section III explains the proposed password hardened multimodal biometric fuzzy vault. Section IV discusses the experimental results and the security analysis of the vault. Section V presents the conclusion.

## 2 Background

Umut uludag et al [1] uses the concept of fuzzy vault to protect a secret $S$ of 128 bits length. The general notations used in the literature are shown in table I. The $x$ and $y$ coordinates of the iris minutiae and retinal bifurcation feature are used as the locking/unlocking unit ‘$u$’ $(x|y)$ of the vault. The secret key $S$ (128 bits) is added with its CRC code (16 bit) to obtain SC (144 bits). SC is divided into 16 bit segments to obtain the polynomial coefficients. Two sets namely, the Genuine set (G) and chaff set (C) are generated.

$$C = [(u_1, p(u_1), (u_2, p(u_2)), \ldots, (u_M, p(u_M)),$$

$$C' = [(c_1, d_1), (c_2, d_2), \ldots, (c_N, d_N)]$$

$$c_i \neq u_i, (j = 1, 2, \ldots, M, t = 1, 2, \ldots, N)$$

$$d_j \neq P(c_j), j = 1, 2, \ldots, M.$$  

$$VS = \text{Listscrabled } (G \cup C)$$

During decoding process, query minutiae set (Q) is compared with the vault to isolate the genuine point set. These points are used to reconstruct the polynomial. The coefficients are mapped back and SC* is obtained. SC* is divided by the CRC primitive polynomial. If the Remainder is not zero, Query template (Q) does not match and the secret decoded is not correct. If the Remainder is zero, Query Template (Q) matches and the Secret(S) is decoded successfully.

The same idea is used for retina and the retinal bifurcation points acts as lock/unlock data. The security of the fuzzy vault depends on the infeasibility of the polynomial reconstruction and the number of chaff points. Using this construct, 128 bit secret data like Advanced Encryption Standard (AES) key can be protected.

Iris based hard fuzzy vault proposed by Srinivasa Reddy [3] applies a sequence of morphological operations to extract minutiae points from the iris texture. This idea is utilized for extracting the locking/unlocking unit from the iris.

To identify the bifurcation feature point on the retinal texture the method proposed by Li Chen [16] is utilized. Section 3 presents the proposed password hardened multimodal biometric fuzzy vault.
3 Proposed Method

The proposed work constructs the password hardened multimodal fuzzy vault in three steps. In the first step the retinal biometric template and iris template are subjected to random transformation using password separately. This process enhances the user privacy and facilitates the generation of revocable templates that resists cross matching. This transformation reduces the similarity between the original and transformed template.

In the second step, multimodal fuzzy vault is constructed to secure the transformed templates. The key used in fuzzy vault construction is randomly generated and transformed using the same password. The key can also be generated from the retinal structure or from the iris features for better security.

In the third step, the vault is encrypted by the key derived from the password. In this vault, password acts as an additional layer of security.

3.1 Extraction of Feature point from Iris and Retina

The following operations are applied to the iris images to extract lock/unlock data. Canny edge detection is applied on iris image to deduct iris. Hough transformation is applied first to iris/sclera boundary and then to iris/pupil boundary. Then threshold is done to isolate eyelashes. Histogram equalization is performed on iris to enhance the contrast.

The following sequence of morphological operation is performed on the enhanced iris structure.

(i) closing-by-tophat
(ii) opening
(iii) thresholding

Finally thinning is done to get structures as a collection of pixels. Now the \((x, y)\) coordinates of the nodes The proposed work uses the idea of Li Chen [16] for extracting the bifurcation structure from retina. Thinning and joining morphological operations are performed on the retinal texture. These operations highlight the retinal vascular patterns. Then the bifurcation feature points are extracted from the vascular patterns. The \((x, y)\) co-ordinates of the iris minutiae and bifurcation feature points of the retina act as lock/unlock data for the vault. Fig 2(a) shows the iris image and Fig 2(b) shows the iris template with highlighted minutiae points.

Fig. 5 Multi Biometric Fuzzy Vault: Decoding
Fig. 2(a) shows the localized iris image and Fig. 2(b) exhibits the iris image with the minutiae patterns. Fig. 3(a) shows the retina image Fig. 3(b) shows the retinal vascular tree and Fig. 3(c) shows the vascular pattern after thinning and joining operation. Fig. 3(d) highlights the retinal template with bifurcation points.

3.2 Implementation of password hardened multi modal fuzzy vault.

The proposed system is implemented in Matlab 7.0. Iris samples are taken from CUHK Iris Image Dataset [10]. Both the images are resized to 256 x 256 grey scale image by bilinear interpolation for further processing. Retina samples are taken from DRIVE database. The retinal images taken from the DRIVE database are resized to the standard 256 x 256 format.

This implementation identifies the lock/unlock data by highlighting the iris minutiae and retinal bifurcation structures. The (x, y) attributes, of the iris minutiae and retina bifurcation structure, where ‘x’ and ‘y’ represents the row and column indices of the both the biometric images are found out. Permutation and Translation operations are applied on the minutiae point and bifurcation feature points by using the password separately. The transformed feature points are protected in the combined fuzzy vault. In this implementation 128 bit random key is generated. This key can also be generated from the retinal structure or from the iris for added security. This key is transformed by the 64 bit user password and is used to encrypt the vault.

3.3 Feature Point Transformation

The iris template and retinal vascular tree containing the highlighted bifurcation feature points are subjected to simple permutation and translation. Fig. 2(b) shows the minutiae before transformation and Fig. 2(c) shows minutiae after transformation for iris. Fig. 3(d) shows the feature point before transformation and Fig. 3(e) shows the feature point after transformation for retina. This results in the original feature points being transformed into new points.

The user password is restricted to the size of 8 characters. Therefore, the length of the password is 64 bits. These 64 bits are divided into 4 blocks of each 16 bits in length. Each 16 bit password block is split into two components T_x of 7 bits and T_y of 9 bits in length. T_x and T_y represent the amount of translation in the horizontal and vertical directions, respectively.

The new feature points are obtained by the following transformation.

\[
\begin{align*}
X' & = (X + T_x) \mod (2^7) \\
Y' & = (Y + T_y) \mod (2^9)
\end{align*}
\]

Where X_x and X'_x are the horizontal distance before and after transformation respectively. Similarly Y_y and Y'_y are the vertical distance before and after transformation respectively. This transformation is applied for both iris and retina template.

3.4 Encoding

The transformed features are encoded in the multi biometric fuzzy vault. Password acts as an extra layer of security to the multi biometric vault. It resists an imposter from modifying the vault. The minutiae points from iris and bifurcation points from retina are combined together. Secret message is generated as a 128 bit random stream. This secret message is transformed with the password. The 16 bit CRC is appended to transformed key S to get 144 bit SC. The primitive polynomial considered for CRC generation is

\[
\bar{g}_{16}(d) = d^{16} + d^{15} + d^{2} + 1
\]

In the combined set, the minutiae points whose Euclidian distance is less than D are removed. 16 bit lock/unlock unit ‘u’ is obtained by concatenating x and y (each 8 bits) coordinates. The ‘u’ values are sorted and first N of them are selected. The Secret (SC) is divided into 9 non overlapping segments of 16 bits each. Each segment is converted to its decimal equivalent to account for the polynomial coefficients \(C_8, C_7 \ldots C_0\). All operations takes place in Galois Field GF(216).

The projection of ‘u’ on polynomial ‘p’ is found. Now the genuine points set G is (ui, P(ui)). Random chaff points are generated which are 10 times in number that of the genuine

3.5 Decoding

In the authentication phase, the encrypted vault and bifurcation feature point are decrypted by the user password. Password based transformation is applied to the query feature points and the vault is unlocked.

From the query templates of the iris and retina, unlocking points (N in number) are extracted. The unlocking set is found as in encoding. This set is compared with the vault to separate the genuine point set for polynomial reconstruction. From this set, all combinations are tried to decode the polynomial. Lagrangian interpolation is used for polynomial reconstruction. For a specific combination of feature points the polynomial gets decoded.

In order to decode the polynomial of degree 8, a minimum of at least 9 points are required. If the combination set contains less then 9 points, polynomial cannot be reconstructed. Now the coefficients and CRC are appended to arrive at SC*. Then SC* is divided by the CRC primitive polynomial.

If the remainder is zero, query image does not match template image and the secret data cannot be extracted. If the remainder is not zero, query image matches with the template image and the correct secret data can be extracted. In this case SC* is divided into two parts as the 128 bit secret data and 16 bit CRC code.

**Parameters used in implementation**

The parameters used in this implementation are shown in Table II. Chaff points hide the genuine points from the attacker. More chaff points makes the attacker to take much time to compromise the vault but consumes additional computation time. The chaff points added are 10 times in number that of the genuine points.

4 Experimental Results And Security Analysis

The vertical and horizontal distances of the retinal bifurcation features and iris minutiae are used for the polynomial projections. The retinal and finger print template is transformed for three different user passwords to check for revocability. Tables III and IV show the sample iris minutiae point and the sample retinal bifurcation points from four quadrants after transformation using three different user passwords ‘security’, ‘template’ and ‘quadrant’ respectively. Fig.6 and Fig.7 illustrate the password transformations.

Consider a 8 character user password ‘security’, the ASCII value of which is given by (115, 111, 99, 117, 114, 105, 116, 121) or 64 bits. These 64 bits are divided into four blocks of 16 bits each and these are further divided into 7 bits and 9 bits for transformation in horizontal and vertical directions respectively. Fig.6 and Fig.7 illustrate the password transformations.

The feature point transformation is done with other two user passwords namely ‘template’ and ‘quadrant’ whose ASCII codes are (116, 101, 109, 112, 108, 97, 116 101) and (113, 117, 97, 100, 114, 97, 110, 116) respectively. For the same original template different transformed templates are obtained when password is changed. This
property of hardened fuzzy vault facilitates revocability. Different passwords can be utilized for different applications to avoid cross matching.

In the proposed method the security of the fuzzy vault is measured by min-entropy which is expressed in terms of security bits. According to Nanda Kumar [7] the min-entropy of the feature template MT given the vault V can be calculated as

\[
H_{\text{w}}(M^T | V) = -\log_2 \left( \begin{pmatrix} r+n+1 \\ r+c \\ n+1 \end{pmatrix} \right)
\]

Where
\[
\begin{align*}
  & r = \text{number of genuine points in the vault} \\
  & c = \text{number of chaff points in the vault} \\
  & t = \text{the total number of points in the vault (} r + c \text{)} \\
  & n = \text{degree of the polynomial}
\end{align*}
\]

The security of the single modal iris, retina and multi modal vault is tabulated in Table V. In order to decode a polynomial of degree \( n \), \( (n+1) \) points are required.

The security of the fuzzy vault can be increased by increasing the degree of the vault. Polynomial with lesser degree can be easily reconstructed by the attacker. Polynomial with higher degree increases security and requires lot of computational effort. This makes more memory consumption and makes the system slow. However they are hard to reconstruct. In the case of the vault with polynomial degree \( n \), if the adversary uses brute force attack, the attacker has to try total of \( (t, n+1) \) combinations of \( n+1 \) element each. Only \( (r, n+1) \) combinations are required to decode the vault. Hence, for an attacker to decode the vault it takes \( C(t, n+1)/C(r, n+1) \) evaluations. The guessing entropy for an 8 ASCII character password falls in the range of 18 – 30 bits. Therefore, this entropy is added with the vault entropy. The security analysis of the password hardened multi biometric fuzzy vault is shown in Table V.

If the number of feature points is less than \( (n+1) \) then Failure to Capture Rate occurs. (FTCR). Multi modal biometric fuzzy vault minimizes the FTCR.

### 5. Conclusion

</tbody>
</table>
Password hardening of the multi biometric fuzzy vault introduces two layers of security namely password and biometrics. Even if the attacker gains the password, he/she may not be able to access the genuine feature points. It is computational very hard for an attacker to identify the genuine feature points. Vault can be captured by the attacker only if he compromises both the biometrics and password simultaneously. This is not possible in real life situation. Hence the proposed password hardened multi biometric fuzzy vault is robust against stored biometric template attacks. The performance of the vault can be improved by the application of soft biometrics, non–invertible transformation and multiple biometric traits. User convenience is increased by combining both iris and retinal capturing cameras in a single device.
